The Wnt signaling cascade is a central regulator of cell fate determination during embryonic development, whose deregulation contributes to oncogenesis. Naked cuticle is the first Wnt-induced antagonist found in this pathway, establishing a negative-feedback loop that limits the Wnt signal required for early segmentation. In addition, Naked cuticle is proposed to function as a switch, acting to restrict classical Wnt signaling and to activate a second Wnt signaling pathway that controls planar cell polarity during gastrulation movements in vertebrates. Little is known about the biochemical function of Naked cuticle or its regulation. Here we report that PR72, a Protein Phosphatase type 2A regulatory subunit of unknown function, interacts both physically and functionally with Naked cuticle. We show that PR72, like Naked cuticle, acts as a negative regulator of the classical Wnt signaling cascade, establishing PR72 as a novel regulator of the Wnt signaling pathway. Our data provide evidence that the inhibitory effect of Naked cuticle on Wnt signaling depends on the presence of PR72, both in mammalian cell culture and in Xenopus embryos. Moreover, PR72 is required during early embryonic development to regulate cell morphogenetic movements during body axis formation.

terior–posterior body axis, which is similar to phenotypes observed for overexpression of known Wnt inhibitors. In line with this, the induction of a secondary body axis in Xenopus embryos induced by ectopic Wnt signaling can be blocked by coinjection of Nkd mRNA (Zeng et al. 2000).

A second Wnt signaling cascade diverges at the level of dishevelled from the canonical (β-catenin-dependent) Wnt signaling cascade to specify asymmetric cell polarity and tissue organization [for review, see Shulman et al. 1998]. This planar cell polarity (PCP) pathway depends on the dishevelled-mediated activation of JNK kinase (Boutros et al. 1998), which involves relocalization of dishevelled to the plasma membrane [Axelrod et al. 1998] and activation of the Rac, and Rho GTPases [Habas et al. 2003]. In contrast to generating a negative-feedback loop in the classical Wnt signaling cascade, it was suggested that Nkd misexpression positively influences the PCP pathway [Yan et al. 2001a]. Consistent with this, Nkd interacts with dishevelled (Rousset et al. 2001; Yan et al. 2001a) and is therefore located at the branchpoint where the classical and PCP pathways diverge [Boutros and Mlodzik 1999]. In contrast to these findings, Naked was also found to mimic loss-of-function dishevelled (Rousset et al. 2001), raising the possibility that ectopic Naked sequesters dishevelled into an inactive complex. This finding is substantiated by the fact that Naked mutant flies have no apparent defect in wing cell polarity [Zeng et al. 2000].

A third signaling pathway under the control of Wnt ligands is the less well-defined Wnt/Ca2+ pathway [Miller et al. 1999a; Kuhl et al. 2000]. Here Wnt-activated frizzled receptors control the release of Ca2+, thereby regulating Ca2+-sensitive enzymes such as Ca2+-calmodulin dependent kinase [CamKII] and protein kinase C (PKC). This pathway also requires dishevelled as a key regulator [Sheldahl et al. 2003]. Naked cuticle contains two recognizable domains of interest, a calcium-binding EF-hand (EFX) domain and a zinc-binding domain. These were found to contribute to Nkd function and dishevelled binding in vitro and in vivo [Wharton et al. 2001; Rousset et al. 2002]. Apart from these observations, the biochemical function of Nkd, as well as any possible upstream regulation, remains illusive.

Understanding the precise regulation of the Wnt regulatory feedback mechanism is essential to understanding the role of this pathway in embryonic development and its aberrant activation leading to a diverse spectrum of human cancers [Polakis 2000; Giles et al. 2003]. Here we show an unexpected role for PR72 [Hendrix et al. 1993; Janssens et al. 2003], an EFX domain-containing regulatory subunit of Protein Phosphatase 2A [PP2A], in the regulation of the Wnt signaling cascade through its interaction with Naked cuticle.

Results

PR72 interacts with Naked cuticle

PP2A is a multifunctional phosphatase holoenzyme involved in numerous cellular processes [for review, see Schonthal 1998; Millward et al. 1999]. Multiple families of PP2A regulatory B-subunits confer substrate specificity to the PP2Ac (catalytic)/PR65 (structural) core phosphatase complex by mediating interactions with specific substrates. One such regulatory B-subunit of unknown function is PR72 [Hendrix et al. 1993]. To begin to characterize the function of this subunit, we performed a yeast two-hybrid screen using human PR72 as bait. Only one interacting protein was identified, which after DNA-sequence analysis was found to encode the mouse ortholog of Drosophila Naked cuticle (Fig. 1A).

We subsequently cloned the two human orthologs of Naked cuticle (hNkd1 and hNkd2) from a human placental cDNA library and generated expression constructs of hNkd1 and hNkd2 fused to a Flag-epitope tag. We found that hNkd1 (Fig. 1B) and hNkd2 (data not shown) share the ability to interact with PR72 in coimmunoprecipitation assays in human embryonic kidney (HEK) 293 cells. No direct interaction was found between PR72 and other components of the Wnt signaling cascade such as dishevelled and GSK3β in coimmunoprecipitation assays (data not shown) and APC in yeast two-hybrid assays [Seelig et al. 1999].

Since PR72 binds to Naked and is a proposed targeting subunit of the PP2A holoenzyme [Hendrix et al. 1993], we asked if PR72 could function as a bridging factor between Naked and the PR65/PP2Ac core dimer. We

Figure 1. PR72 interacts with Naked cuticle. (Upper right) Negative controls Gal4/PR72 and vector-TA or Gal4-vector and Naked-TA do not stain positive. (Left two panels) The positive control is Gal4-p107 and adenovirus E1A-TA. (B) Immune precipitation of PR72 and Naked cuticle. (Upper right) Extracts from HEK 293 cells ectopically expressing Flag-tagged hNkd1 or HA-tagged hPR72 or both were subjected to immunoprecipitation with anti-Flag and anti-HA antibodies as indicated. HA-antibodies did not precipitate PR72 and Naked cuticle. (Lower right) Negative controls Gal4-PR72 and vector-TA or Gal4-vector and Naked-TA do not stain positive. (Left two panels) The positive control is Gal4-p107 and adenovirus E1A-TA. [C] Immune precipitation of PR72 and Naked cuticle. (Upper right) Extracts from HEK 293 cells ectopically expressing Flag-tagged hNkd1 or HA-tagged hPR72 or both were subjected to immunoprecipitation with anti-Flag and anti-HA antibodies as indicated. HA-antibodies did not precipitate Flag-Naked (first lane) and the Flag antibody did not precipitate HA-PR72 (third lane), when coexpressed both were coprecipitated with either anti-HA or anti-Flag (second and fourth lanes). The background in the upper section of the Flag-Naked IP is the Ig heavy chain running at the same height as Flag-Naked. The lower panel shows 10% of the total lysate used in each of the immunoprecipitations. [C, right two panels] Immune precipitation of Naked cuticle and the PP2Ac/PR65 core dimer in HEK 293 cells in the presence (right) or absence (left) of HA-PR72. The left two panels show 10% of the total lysate.
transfected HEK 293 cells with constructs expressing Flag-hNkd1, HA-PR65, and HA-PP2Ac in the presence or absence of HA-PR72 and performed coimmunoprecipitation assays for Flag-Naked cuticle. We found that hNkd1 could form a complex with the PP2A only in the presence of PR72, indicating that PR72 is required as a bridging factor between Naked and the PR65/PP2Ac core dimer (Fig. 1C). These results demonstrate that PR72 can interact with Naked cuticle and facilitates recruitment of the PP2A/PR65 core dimer to the complex.

**PR72 is a negative regulator of the classical Wnt signaling pathway**

Since Naked cuticle is an established negative regulator of the canonical Wnt signaling cascade, we addressed the question if PR72 functions as a mediator of the Wnt signaling pathway as well. Figure 2A shows that ectopic expression of PR72 represses a Wnt-1-responsive TCF site-containing luciferase reporter construct (Top-Glow) in HEK 293 cells (which respond to Wnt signaling and in which the pathway has a low basal activity) [Jho et al. 2002; Valenta et al. 2003], but not a Fop-Glow reporter of this active form of β-catenin. It was shown in a similar experimental setup to its destruction by the proteasome in the absence of a phospho-site mutant β-catenin as indicated. Luciferase activities were determined. (C) Western blot showing lysates of non-Wnt-1-stimulated HEK 293 cells transfected with or without HA-PR72 (lanes 2,3) and repeated after overnight treatment with 10 mM of LiCl (lanes 3,4). Blots were probed with anti-HA (upper panel) or anti-β-catenin (lower panel). (D) Efficiency of the knock-down constructs was determined by cotransfection of 5 µg of the shRNA vectors with a mix of 2 µg of CMV HA-PR72, CMV HA-PR55, and CMV-GFP in a ratio of 1:1:1, one of which was the target for suppression. Forty-eight to seventy-two hours post-transfection, lysates were subjected to Western blot analysis with either anti-HA or anti-Flag and then reprobed with anti-GFP antibodies (l.c.) to determine protein levels. (E) One-hundred nanograms of TCF containing Top-Glow or Fop-Glow (containing mutated TCF sites) luciferase reporter, 50 ng of CMV Renilla luciferase, and 5 ng of CMV-Wnt-1 was cotransfected in HEK 293 cells with or without 0.5 µg of CMV HA-PR72 or CMV HA-PR55 as indicated. (B) As in A, in the presence of either 100 ng of empty vector or phospho-site mutant β-catenin as indicated. Luciferase activities were determined. (D) Efficiency of the knock-down constructs was determined by cotransfection of 5 µg of the shRNA vectors with a mix of 2 µg of CMV HA-PR72, CMV HA-PR55, and CMV-GFP in a ratio of 1:1:1, one of which was the target for suppression. Forty-eight to seventy-two hours post-transfection, lysates were subjected to Western blot analysis with either anti-HA or anti-Flag and then reprobed with anti-GFP antibodies (l.c.) to determine protein levels. (E) One-hundred nanograms of TCF containing Top-Glow or Fop-Glow (containing mutated TCF sites) luciferase reporter, 50 ng of CMV Renilla luciferase, and 5 ng of CMV-Wnt-1 was cotransfected in HEK 293 cells with 2 µg of either an empty pSUPER (pS) or one containing a PR72 targeting shRNA (pS-PR72) or a PR55 targeting shRNA, as indicated.

Figure 2. PR72 is a repressor of the canonical Wnt pathway. (A) One-hundred nanograms of TCF containing Top-Glow or Fop-Glow [containing mutated TCF sites] luciferase reporter, 50 ng of CMV Renilla luciferase, and 5 ng of CMV-Wnt-1 was cotransfected in HEK 293 cells with or without 0.5 µg of CMV HA-PR72 or CMV HA-PR55 as indicated. (B) As in A, in the presence of either 100 ng of empty vector or phospho-site mutant β-catenin as indicated. Luciferase activities were determined. (C) Western blot showing lysates of non-Wnt-1-stimulated HEK 293 cells transfected with or without HA-PR72 (lanes 1,2) and repeated after overnight treatment with 10 mM of LiCl (lanes 3,4). Blots were probed with anti-HA (upper panel) or anti-β-catenin (lower panel). (D) Efficiency of the knock-down constructs was determined by cotransfection of 5 µg of the shRNA vectors with a mix of 2 µg of CMV HA-PR72, CMV HA-PR55, and CMV-GFP in a ratio of 1:1:1, one of which was the target for suppression. Forty-eight to seventy-two hours post-transfection, lysates were subjected to Western blot analysis with either anti-HA or anti-Flag and then reprobed with anti-GFP antibodies (l.c.) to determine protein levels. (E) One-hundred nanograms of TCF containing Top-Glow or Fop-Glow [containing mutated TCF sites] luciferase reporter, 50 ng of CMV Renilla luciferase, and 5 ng of CMV-Wnt-1 was cotransfected in HEK 293 cells with 2 µg of either an empty pSUPER (pS) or one containing a PR72 targeting shRNA (pS-PR72) or a PR55 targeting shRNA, as indicated.

induced degradation of β-catenin. It is therefore likely that PR72, like Nkd, uses the canonical Wnt-signaling cascade to regulate cytoplasmic levels of β-catenin.

Since increasing the levels of PR72 inhibited Wnt signaling, we next asked if reducing the levels of endogenous PR72 could stimulate Wnt signaling. For this purpose, we generated short hairpin RNA (shRNA) expression vectors [Brummelkamp et al. 2002b] specifically targeting PR72 or PR55 and tested their ability to inhibit the expression of their cognate targets. We found
that both constructs were able to effectively reduce protein levels of their corresponding targets when cotransfected into HEK 293 cells (Fig. 2D). When tested for activity on a Top-Glow reporter, we found that knockdown of endogenous PR72, as opposed to ectopic PR72 expression, stimulated the Wnt signaling pathway in HEK 293 cells (Fig. 2E), while no such effect was found for PR55x knock-down. These results demonstrate that PR72, like Naked cuticle, is a negative regulator of the classical Wnt signaling pathway in cell culture.

Naked cuticle depends on PR72 for its antagonizing function

We generated shRNA-expressing constructs specific for hNkd1 and hNkd2 and tested their ability to suppress expression of their cognate targets when ectopically co-expressed in tissue culture. We found that both constructs were specific and effective in reducing target protein levels (Fig. 3A). As expected, suppression of endogenous hNkd1 and hNkd2 by shRNA activated Wnt signaling in HEK 293 cells (Fig. 3B). This result is in good agreement with previous results obtained in mouse and fly systems (Zeng et al. 2000; Wharton et al. 2001; Yan et al. 2001a), indicating that Nkd contributes to suppression of the Wnt signal.

When we repeated this experiment in the presence of shRNA vectors targeting PR72 and hNkd for suppression, no super-activation of the Top-Glow reporter was observed (Fig. 3B). This suggests that PR72 and hNkd act in a linear pathway to suppress Wnt signaling.

When hNkd is overexpressed, we observed mild, dose-dependent inhibition of the Top-Glow reporter (Fig. 3C). This inhibition is significantly reduced when repeated in the presence of a hairpin vector targeting PR72 for suppression, suggesting that PR72 is required for Naked-mediated repression of the canonical Wnt signaling pathway.

PR72 and Naked regulate dishevelled stability

Since PR72 recruits PP2A to Naked, we asked whether Naked was a target for dephosphorylation by the PP2A catalytic subunit. We could, however, find no evidence

Figure 3. Naked requires PR72 for its function as a Wnt antagonist. [A] Efficiency of knock-down constructs was determined by cotransfection of 5 µg of the shRNA vectors with a mix of 2 µg of CMV Flag-hNkd1, CMV Flag-hNkd2, or CMV-GFP in a ratio of 1:1:1. Lysates were subjected to Western blot analysis with either anti-HA or anti-Flag and then reprobed with anti-GFP antibodies (l.c.) to determine protein levels. [B] One-hundred nanograms of TCF containing Top-Glow or Fop-Glow (containing mutated TCF sites) luciferase reporter, 50 ng of CMV Remilla luciferase and 5 ng of CMV-Wnt-1 was cotransfected in HEK 293 cells with or without 1 µg of pRS-hNkd1 and 1 µg of pRS-hNkd2 either in the presence or absence of pS-PR72. (C) In a similar experiment, 0, 0.2, or 0.5 µg of CMV-hNkd1 was cotransfected with the Top-Glow reporter in the presence of 2 µg of pS or pS-PR72. (D) Immunoprecipitation for Flag-tagged Naked was done on cell lysates of HEK 293 cells transfected with HA-PR65, HA-PP2Ac, and mDsh1 in the absence or presence of HA-PR72 [every second lane] or Flag-hNkd1 [last four lanes]. (E) Cell lysates of HEK 293 cells containing HA-PR72 and mDsh1 with [last two lanes] or without proteasome inhibitors were subjected to Western blot analysis and probed with antibodies targeting dishevelled. PR72 levels were detected using an anti-HA reprobe. (F) Cell lysates of HEK 293 cells containing HA-PR72 with [last two lanes] or without pRS-Nkd1 were subjected to Western blot analysis and probed with antibodies targeting dishevelled.
to support a role for PR72/PP2A complexes in regulating the phosphorylation of hNkd1 using both $^{32}$P-orthophosphate-labeling experiments and mobility shifts in SDS polyacrylamide gel electrophoresis (data not shown). Alternatively, PR72/PP2A could act on different proteins required for Naked-mediated suppression of Wnt signaling. The only other identified binding partner of Naked cuticle is dishevelled. We therefore asked if the interaction between Naked and dishevelled was affected by PR72. We performed coimmunoprecipitation experiments in HEK 293 cells expressing Flag-Nkd1 and di

**PR72**

PR72/PP2A could act on different proteins required for Naked-mediated suppression of Wnt signaling. The only other identified binding partner of Naked cuticle is dishevelled. We therefore asked if the interaction between Naked and dishevelled was affected by PR72. We performed coimmunoprecipitation experiments in HEK 293 cells expressing Flag-Nkd1 and dishevelled in the presence or absence of ectopic PR72. Surprisingly we found that the Naked–dishevelled interaction was lost upon cotransfection of PR72 (Fig. 3D). Since the direct interaction between Naked and dishevelled is likely to be required for Naked inhibitory function, disruption of this complex should then result in an increase in Wnt signaling rather than the negative effect observed for PR72 in our experiments. We therefore wondered if dishevelled–Naked interaction was truly affected or whether the level of dishevelled protein was reduced in the cell. We found that total dishevelled protein levels, both ectopic [Fig. 3E] and endogenous [Fig. 3F], were reduced upon introduction of PR72. Addition of proteasome inhibitors prevented the PR72-induced loss of dishevelled. This was seen both for the total amount of cellular dishevelled [Fig. 3E] and for dishevelled protein in complex with Naked [Fig. 3D]. These results suggest that PR72 bound to Naked functions as a regulator of dishevelled protein levels. Analysis of dishevelled phosphorylation status did not reveal a correlation between PR72 expression and dephosphorylation of dishevelled, suggesting that its deregulation by PR72 is likely to be indirect (data not shown).

**XPR72**

**XPR72** is required for gastrulation movements and somite differentiation and development of the eye during *Xenopus* embryonic development

To test the biological relevance of our findings, we investigated the role of PR72 during early embryonic development of *Xenopus tropicalis*, a well-established model for studying Wnt signaling during development. We identified the EST homologous to the 5′ amino acid sequence coding for human PR72 from the JGI *X. tropicalis* database (http://www.jgi.doe.gov) and generated oligonucleotides to evaluate expression of XPR72 by RT–PCR at different stages of embryonic development. Figure 4A [upper panel] shows that PR72 is maternally expressed and is present during all stages of early embryonic development. Later during development at the tadpole stage we find that PR72 is mainly expressed in somites as judged by whole-mount in situ hybridization

![Image](https://via.placeholder.com/150)

Fig. 4A, lower panel], which is in concert with results from human tissue blots showing high PR72 RNA in heart and skeletal muscle [Hendrix et al. 1993]. Notably, Xnkδ is also expressed in the somites [data not shown], which could support a possible connection between PR72 and Nkd function in this tissue.

We generated morpholino oligonucleotides (MO) that specifically inhibit translation of RNA from the *X. tropicalis* ortholog of PR72. To restore PR72 RNA in the knock-down embryos, we used human PR72 RNA, which is insensitive to the XPR72 MO due to five mismatches compared to the corresponding *Xenopus* sequence. We find that depletion of XPR72 with two distinct sets of PR72 MOs causes severe developmental defects, while similar amounts of control MO show no developmental defects. PR72-depleted embryos do not move or swim, which is indicative of differentiation defects of the somites forming the muscle cells. These embryos show a short axis phenotype [Fig. 4B] with a structure reminiscent of an open blastopore caudally [Fig. 4B, arrowheads], which is most likely due to incomplete closure of the blastopore during late gastrulation and indicates an effect on morphogenetic cell movements required for elongation of the body axis. A low frequency of neural tube closure defects [Fig. 4B, arrows] also indicates defects in morphogenetic cell movements during gastrulation. This might link PR72 to dishevelled function in development since defects in morphogenetic cell movements during gastrulation were also described for embryos overexpressing dishevelled [Wallingford et al. 2000]. Less expected was the lack of differentiated eyes [Fig. 4C, white arrows]. However, ectopic expression of Wnt in the developing anterior neural tissue was previously shown to result in loss of eye formation as shown in the zebrafish *Axin1* mutation *masterblind* [van de Water et al. 2001].

The formation of the somites can be monitored by analyzing the expression of the muscle-specific gene *XmyoD*. Whole-mount in situ hybridization for *XmyoD* on embryos injected with PR72 MO suggests that the somites were smaller than in control embryos [Fig. 5A]. When we injected only one side (either left or right) of the embryos at the four-cell stage, embryos were strongly bent to one side [Fig. 4C]. We used the loss of eye formation to identify the side of injection. This demonstrates that the injected side of the embryo [without the eye] was much shorter than the control side, which could indicate a developmental defect of the somites. We could rescue this phenotype for 80% when we coinjected hPR72 RNA [Fig. 4D], demonstrating that the developmental defects were, indeed, caused by PR72 depletion.

To find evidence for a cooperative function of PR72 with Nkd, we performed double knock-down for PR72 and Nkd with low MO doses, which gave no obvious phenotype when injected alone [data not shown]. When we injected the same low amount of PR72 and Nkd MO together, we found embryos with similar phenotypes as we found with higher doses PR72 MO alone [Fig. 5A]. This additive effect strongly suggests cooperation between PR72 and Nkd during *Xenopus* development.
PR72 is required for Naked cuticle to antagonize an ectopic Wnt signal in Xenopus

To test in a vertebrate model system if PR72 is, indeed, required for the antagonistic function of Nkd in the canonical Wnt signaling pathway, we used the Wnt-induced second axis assay in *Xenopus*. Using this assay the antagonistic function of Nkd on the canonical Wnt signaling pathway was demonstrated previously by showing that coexpression of Naked rescues the formation of a Wnt-induced secondary body axis (Zeng et al. 2000). We used this assay to investigate the role of PR72 in Nkd-mediated inhibition of Wnt by coinjecting the hNkd RNA on the ectopic Wnt signal (data not shown).

To demonstrate the specificity of the effect of XPR72 depletion on Nkd function as described above, we restored the level of PR72 by coinjection of human PR72 mRNA, which is insensitive to the PR72 MO. This rescued the antagonizing function of hNkd1 on the Wnt signaling pathway (Fig. 5D). These results are consistent with those obtained in cell culture in vitro, and provide evidence that PR72 is required for Naked cuticle to antagonize the canonical Wnt signaling pathway in vertebrates in vivo.

Discussion

We report here that hPR72, a PP2A B regulatory subunit of previously unknown function, interacts with Naked cuticle, an inhibitor of the canonical Wnt signaling cascade. Naked cuticle was previously identified as an important protein to restrict Wnt signaling in cell culture and during embryonic development (Zeng et al. 2000; Rousset et al. 2001; Yan et al. 2001a). It was subsequently found that Naked cuticle interacts with dishevelled, one of the major orchestrators of the various Wnt-driven cascades (Wharton 2003), thereby placing the gene
physically in the Wnt signaling cascade, but leaving its molecular regulation illusive. We find that PR72 binds to and is required for the antagonistic effects of Nkd on Wnt signaling, demonstrating that PR72 is a new modulator of Wnt signaling. PR72, like Nkd, antagonizes the canonical Wnt signal in cell culture. Conversely, loss of PR72, like loss of Nkd, results in activation of the canonical Wnt signaling cascade. Additionally, we found that both PR72 and Naked cuticle are negative regulators of dishevelled protein levels, providing a possible mechanism for their inhibitory actions on the Wnt signaling cascade.

The data obtained in cell culture were confirmed in vivo using the Xenopus second axis assay as a vertebrate model system. We found that XPR72 depletion abolished the inhibitory function of Nkd on Wnt signaling in Xenopus embryos, demonstrating that Nkd requires PR72 to modify the canonical Wnt signaling pathway. We subsequently studied the effects of PR72 depletion in untreated Xenopus embryos and found that PR72 is required for morphogenetic cell movements during gastrulation and proper development of the somites and eyes. Gastrulation defects were previously described for Xenopus embryos overexpressing wild-type or a dominant negative form of dishevelled [Wallingford et al. 2000; Yan et al. 2001a], suggesting tight regulation of dishevelled levels is a prerequisite for correct gastrulation movements. Since we find deregulation of dishevelled protein levels in cell culture by PR72, it's possible this effect contributes to the defects observed during development in PR72-depleted Xenopus embryos. Although PR72 RNA is maternally expressed, we did not find evidence that PR72 is required for the cytoplasmic canonical Wnt signal early in development to establish the dorsal–ventral (D/V) body axis. This might not be surprising since maternal Dsh protein is enriched at the dorsal side in an early Xenopus embryo by cortical rotation just after fertilization [Miller et al. 1999b, for review, see Weaver and Kimmel 2004]. In agreement with this, Dsh overexpression at the dorsal side was reported not to affect D/V axis specification but convergence and extension [Wallingford et al. 2000]. The relatively mild gastrulation defects in PR72-depleted embryos compared to the Dsh overexpression phenotype [Wallingford et al. 2000] might also be due to a more modest increase in Dsh levels by PR72 depletion as compared to the levels obtained by ectopic injection of Dsh RNA.

Formation of the somites to divide the vertebrate body axis in segments is established by a process in which blocks bud off from the unsegmented presomitic mesoderm in an anterior to posterior fashion (for review, see Aulehla and Herrmann 2004). The Wnt signaling pathway, among other signaling pathways, plays a role in establishing the dorsal to ventral polarity of the somites [Takada et al. 1994; Fan et al. 1997; Lee et al. 2001] and in regulating the segmentation clock [Aulehla et al. 2003]. The self-inhibitory feedback mechanism between Axin2 and the Wnt signal controls the oscillation of Axin2 levels and consequently the rhythmic switching between an active and inactive Wnt signal during elongation of the body axis [Aulehla et al. 2003]. This mechanism was shown to contribute to the segmented formation of distinct blocks of somites. Naked and Axin2 are both Wnt-inducible antagonists and are both present in somites [data not shown]. This coregulation is also observed in tumors with an activated Wnt signal [Yan et al. 2001b]. It is therefore tempting to speculate that both Naked and Axin2 contribute to this segmentation effect during somite development. This could, in turn, account for the somitogenesis defects observed in our PR72/Nak-
PR72 regulates Wnt signaling

PR72 regulates Wnt signaling

The lack of eye development in the PR72 MO-injected embryos resembles the masterblind mutation in zebrafish embryos in which Wnt is ectopically activated due to loss of Axin1 function (van de Water et al. 2001). Similarly to the defects in somitogenesis, one could speculate that repression of the Wnt signal in this context is due to the action of both Naked and Axin, but a definite link between the two remains to be determined. In summary, loss of PR72 in Xenopus embryos results in several developmental defects that are phenotypically similar to those that result from alterations in Wnt signaling. The phenotype caused by depletion of PR72 is different from depletion of another PP2A regulatory subunit, B56e. While B56e is required for specification of the dorsal side during embryogenesis, PR72 is required for correct cell morphogenetic movements during gastrulation and somite development. This underscores the specificity of regulatory subunits of PP2A to correctly modulate different outcomes using the same core unit in different developmental processes.

Our data suggest a role for both PR72 and Naked in negative regulation of dishevelled stability. This would be in agreement with reported similarities between the phenotypes caused by ectopic Naked expression and dishevelled loss-of-function mutants in embryogenesis [Rousset et al. 2001]. We find that loss of Naked cooperates with loss of PR72 in disturbing cell morphogenetic movements during gastrulation, which could represent a polarity defect. Since both PR72 and Naked cuticle are negative regulators of dishevelled protein levels, it is difficult to see how either would function as an activator of the PCP pathway as was proposed by Yan et al. (2001a). Indeed, the role of Naked cuticle in PCP is still under debate, since loss of Nkd does not affect cell polarity in the Drosophila wing (Zeng et al. 2000) and Naked misexpression is indistinguishable from dishevelled loss-of-function mutants (Rousset et al. 2001).

It has previously been described that both introducing exogenous dishevelled and interfering with endogenous dishevelled by introduction of a dominant negative mutant can cause defects in cell morphogenetic movements during gastrulation (Wallingford et al. 2000). This result not only underscores the importance of tight regulation of dishevelled levels during development but also makes it difficult to conclude whether the observed defects in gastrulation observed by Yan et al. (2001a) caused by Naked misexpression are the result of an overactive PCP pathway or a defect in this pathway. We propose that PR72 and Naked cuticle are negative regulators of both the canonical and the PCP pathways.

Since PP2A regulatory subunits are generally involved in providing substrate specificity to the holoenzyme (Schonthal 1998; Millward et al. 1999), the most straightforward interpretation of our data is that Naked cuticle is the substrate for the PP2A phosphatase. Support for a role as a PP2A-targeting subunit comes from the finding that the PP2A holoenzyme can form a complex with Naked cuticle in a PR72-dependent manner. However, we did not find an effect of PR72 overexpression or its knock-down on the general phosphorylation status of Nkd as judged by [32P]-orthophosphate labeling in HEK 293 cells or alterations in its mobility in SDS-PAGE (data not shown). We cannot exclude that only one of multiple phosphorylation sites on hNkd is regulated by PR72, which would be masked in an assay addressing overall phosphorylation status of hNkd. It is, however, very well possible that other, yet unidentified, proteins interact with Nkd that are targets of the PR72/PP2A holoenzyme. If this is the case, Naked cuticle would act as a docking platform that, like dishevelled, brings together multiple proteins involved in the regulation of the different signals through the Wnt cascade (Wharton 2003). It is possible that dishevelled is a direct target for PR72/PP2A complexes. This could be suggested by the finding that PR72 reduces the levels of phosphorylated Dsh [Fig. 3F]. However, we cannot exclude that phosphorylated Dsh is more rapidly degraded, explaining its lower abundance. Furthermore, we found no direct evidence supporting dishevelled dephosphorylation (data not shown) prior to its destruction, suggesting regulation of dishevelled by PR72 is likely to be indirect.

Notably, PR72 and Nkd share EFX calcium-binding domains generally believed to be involved in protein folding. It is tempting to speculate on a role for the Wnt/Ca2+ pathway in the regulation of these two proteins and their interaction. This would further integrate the Wnt/Ca2+ and PCP pathways and also connect to the classical Wnt signaling cascade. It was previously described for PR72 that the two EFX domains, indeed, play a role in protein folding upon binding of Ca2+ (Janssens et al. 2003).

The regulation of Naked cuticle function by PR72 reported here adds a new level of complexity into this illusive antagonist of the canonical Wnt signaling cascade. Correct regulation of this inhibitory response is equally important as positive regulation of the Wnt signal itself, both fine-tuned to orchestrate the extent of the Wnt signal during embryonic development. Conversely, alterations in PR72-dependent signaling might contribute to deregulated Wnt signaling during tumor progression. Indeed, earlier work indicates that PR72 is a negative regulator of cell cycle progression (Janssens et al. 2003). However, it is not clear if this negative effect on cell cycle results from inhibition of Wnt signaling. Consistent with a role for PR72 in oncogenesis is also the finding that binding of PR72 to the PP2A core complex is deregulated in colorectal cancer (Wang et al. 1998; Ruediger et al. 2001). Notably some 80% of human colon cancers arise from deregulated canonical Wnt signaling (Poleakis 2000; Giles et al. 2003). Although no causal relation between deregulation of PR72 and tumor formation has been made, its role in regulating cell cycle and its deregulation in colon tumors provide tempting speculation. Future experiments will have to establish the molecular relation between Naked cuticle, PR72, and regulation of dishevelled and will perhaps bring more insight.
into the mechanism of Wnt signal restriction during embryonic development and oncogenesis.

Materials and methods

Yeast two-hybrid screen

Yeast strain Y190 [Harper et al. 1993] containing “bait” plasmid pPC97-PR72 encoding the GAL4 DNA-binding domain (DBD) fused to full-length hPR72 was transformed with a day 14.5 CD1 mouse embryo library [Chevay and Nathans 1992] by the lithium acetate method [Schiestl and Gietz 1989]. Transformants were selected for growth on plates lacking histidine and supplemented with 25 mM 3-aminotriazole. His+ colonies were tested for bait specificity by retransformation with pPC97 lacking an insert.

Cell lines, transfections, and luciferase assays

293 HEK cells were cultured in Dulbecco’s modified Eagle’s medium supplemented with 10% fetal calf serum, L-glutamine, and penicillin/streptomycin [GIBCO]. Transient transfections in these cells were performed by the calcium phosphate precipitation method [van der Eb and Graham 1980]. Luciferase assays were performed using the Dual luciferase system (Promega). For loss-of-function assays, 2 µg of either pSUPER or pRETO SUPER [Brummelkamp et al. 2002a] was transfected, and luciferase counts were measured 60 h post-transfection using a TD-20/20 Luminoounter (Promega). For gain-of-function assays, 500 ng of CMV construct was cotransfected, and luciferase counts were measured 24 h post-transfection.

Plasmids and reagents

Anti-Flag (m2) was purchased from Sigma; anti-HA [Y11], anti-GFP (FL), anti-β-catenin [H-102], and anti-Dsh1 [3F12] antibodies were purchased from Santa Cruz. PPC97-hNkd1, PPC97-hNkd2, and PPC97-GSK were obtained from Roel Nusse (Department of Developmental Biology, University, Stanford, CA). hNKD1 and hNKD2 were PCR-amplified from a human placental cDNA library [Clonetech] and cloned as BamHI/EcoRV fragments in frame into the pFlag-CMV backbone (Invitrogen). CMV-HA-P2Ac RNA and 10 ng of control morpholino oligo (Genetools), or with 0.5 pg of Wnt-1 RNA and 10 ng of PR72 morpholino oligo (Genetools), or with 0.5 pg of Wnt-1 RNA, 9 pg of Nkd RNA, and 10 ng of PR72 morpholino oligo (Genetools), or with 0.5 pg of Wnt-1 RNA, 8 pg of Nkd RNA, 10 ng of PR72 morpholino oligo, and 10 pg of hPR72 RNA. Dorsal injection was done with 2 ng of PR72 RNA alone, with 0.5 pg of Wnt-1 RNA together with 9 pg of hNkd RNA and 10 ng of control morpholino [Genetools], with 0.5 pg of Wnt-1 RNA, 9 pg of Nkd RNA, and 10 ng of PR72 morpholino oligo [Genetools], or with 0.5 pg of Wnt-1 RNA, 8 pg of Nkd RNA, 10 ng of PR72 morpholino oligo, and 10 pg of hPR72 RNA. Dorsal injection was done with 10 ng of mixed nonoverlapping XPR72 MOs [1, 4, and 5 or 1, 2, and 3] to maximize knock-down efficiency or 10 ng of control MO. After injection, embryos were kept for 6 h in 12% MMR with addition of 3% Ficoll [Amersham Biosciences] at 23°C and subsequently raised in 12% MMR at 23°C. At tailbud stage the
embryos were fixed in MEMPFA [100 mM MOPS [Sigma] at pH 7.4; 2 mM EGTA [Sigma], 1 mM MgSO4 [Merck], 4% paraformaldehyde [Sigma]] and analyzed for the formation of a secondary axis. Embryos were staged according to Nieuwkoop and Faber (1967).

Acknowledgments

We thank Hans Clevers and Roel Nusse for plasmids and Brian Hemmings for antisera against PR72. This work was supported by a grant from the Dutch Cancer Society [KWF] and the European Union Grant QLRT-2000-01275 (G.R.).
